Project Expectations

Please refer back to the **Course Project (https://q.utoronto.ca/courses/444184/pages/project-overview?wrap=1)** page for the high-level description of the project this term.

The project is primarily an opportunity for you to experience working in a collaborative, team environment.

Your team's project is expected to fulfill the following requirements. If your team is unsure if your project will meet any of these, please make sure to ask sooner rather than later so that we can ensure that your project is on track.

- **Your team must demonstrate the use of Pull Requests throughout the development of your project.**
- **Your team must develop a Java program with a Java Swing GUI.**
  - If your team has a compelling reason to use JavaFX instead, please ask and we will consider approving its use.
  - Requests to make some kind of web app will not be approved, as there are other courses dedicated to developing such applications.
- **The scope of your project should align with there being one user story per team member.**
- **Your program must attempt to adhere to Clean Architecture and the SOLID principles.**
  - During your final presentation, your team will be expected to talk about your design and demonstrate the program's functionality. Your team should be prepared to justify any design decisions that you made.
  - We will talk about SOLID in week 6 and then Clean Architecture in weeks 7 and 8.
- **Your team must make use of an external API in your project.**
  - Note: it is fine if your team decides to use a Java library that wraps the actual API calls.
  - The lab in week 7 of the course will discuss APIs.
- **Your program must demonstrate some form of data persistence.**
  - This could be storing data through some kind of API, writing data to files, or writing data to some kind of database.
  - Using the API that is used by the user login system example's **DBUserDataAccessObject class (https://github.com/CSC207-2025F-UofT/ca-user-login/blob/main/src/main/java/data_access/DBUserDataAccessObject.java)** to store and retrieve a "user" and an associated JSON object could satisfy both of the above requirements for API usage and data persistence. This would be appropriate for projects that rely on being able to share data across multiple users across devices, for example.
- **You will each be assessed on your contribution to the team**
  - Each team member is expected to at least take the lead on one Use Case (I.e., your team can divide up work as you wish, but you each need to write the majority of the code for one use case — after Clean Architecture is introduced, it will be clear what this means).
  - Please make sure that you are:

- Attending all labs and any meetings that your team schedules (or communicating with your team if you can't attend something)
- Actively participating on a weekly basis
- Contributing an appropriate amount to your team's GitHub repository
  - We will be checking your team's git logs.
  - Make sure to give everyone an opportunity to contribute code — this means that you should do your fair share and you should not write code that is the responsibility of another team member.
  - **If we don't see code contributions from you, then we can't give you credit for the project.**
  - **If all we see is code from you and nobody else, then we also can't give you credit as it is a group project.**
